# NOT EXISTS

Last modified: Jan 28, 2020

Follow @vlad\_mihalcea

Imagine having a tool that can automatically detect if you are using JPA and Hibernate properly.

[Hypersistence Optimizer](#) is that tool!

## Introduction

In this article, we are going to see how the SQL EXISTS operator works and when you should use it.

Although the EXISTS operator has been available since SQL:86, the very first edition of the SQL Standard, I found that there are still many application developers who don't realize how powerful SQL subquery expressions really are when it comes to filtering a given table based on a condition evaluated on a different table.

## Database table model

Let's assume we have the following two tables in our database, that form a [one-to-many table relationship](#).

The student table is the parent, and the student\_grade is the child table since it has a

student	
<b>id</b>	bigint
<b>admission_score</b>	double precision
<b>first_name</b>	varchar(255)
<b>last_name</b>	varchar(255)

## Hypersistence Optimizer

The student table contains the following two records:

id	first_name	last_name	admission_score
1	Alice	Smith	8.95
2	Bob	Johnson	8.75

## ERP Contact

And, the student\_grade table stores the grades the students received:

id	class_name	grade	student_id
1	Math	10	1
2	Math	9.5	1
3	Math	9.75	1
4	Science	9.5	1
5	Science	9	1
6	Science	9.25	1
7	Math	8.5	2
8	Math	9.5	2
9	Math	9	2
10	Science	10	2
11	Science	9.4	2

## Online Workshop

# SQL EXISTS

Let's say we want to get all students that have received a 10 grade in Math class.

```

6      student_grade.grade = 10 AND
7      student_grade.class_name = 'Math'
8  ORDER BY
9      student_grade.student_id

```

But, the application is interested in displaying the full name of a student, not just the identifier, so we need info from the student table as well.

In order to filter the student records that have a 10 grade in Math, we can use the EXISTS SQL operator, like this:

```

1  SELECT
2      id, first_name, last_name
3  FROM
4      student
5  WHERE EXISTS (
6      SELECT 1
7      FROM
8          student_grade
9      WHERE
10         student_grade.student_id = stud
11         student_grade.grade = 10 AND
12         student_grade.class_name = 'Mat
13 )
14 ORDER BY id

```

When running the query above, we can see that only the Alice row is selected:

id	first_name	last_name
1	Alice	Smith

The outer query selects the student row columns we are interested in returning to the client. However, the WHERE clause is using the EXISTS operator with an associated inner subquery.

The inner subquery is correlated because the `student_id` column of the `student_grade` table is matched against the `id` column of the outer `student` table.

## SQL NOT EXISTS

Let's consider we want to select all students that have no grade lower than 9. For this, we can use `NOT EXISTS`, which negates the logic of the `EXISTS` operator.

Therefore, the `NOT EXISTS` operator returns true if the underlying subquery returns no record. However, if a single record is matched by the inner subquery, the `NOT EXISTS` operator will return false, and the subquery execution can be stopped.

To match all student records that have no associated `student_grade` with a value lower than 9, we can run the following SQL query:

```
1  SELECT
2      id, first_name, last_name
3  FROM
4      student
5  WHERE NOT EXISTS (
6      SELECT 1
7      FROM
8          student_grade
9      WHERE
10         student_grade.student_id = stud
11         student_grade.grade < 9
12     )
13  ORDER BY id
```

Cool, right?

## Online Workshops

If you enjoyed this article, I bet you are going to love my upcoming Online Workshops!

- **High-Performance SQL (4 hours x 2 days)** - October 28-30
- **High-Performance Java Persistence (4 hours x 4 days)** - December 7-10

## Conclusion

The advantage of using the SQL EXISTS and NOT EXISTS operators is that the inner subquery execution can be stopped as long as a matching record is found.
